Abstract: The electrochemical performance of Ta-doped Li$_4$Ti$_5$O$_{12}$ in the form of Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ was characterized. X-ray diffraction (XRD) and scanning electron microscopy (SEM) were employed to characterize the structure and morphology of Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$. Ta-doping does not change the phase composition and particle morphology, while improves remarkably its cycling stability at high charge/discharge rate. Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ exhibits an excellent rate capability with a reversible capacity of 116.1 mA·h/g at 10°C and even 91.0 mA·h/g at 30°C. The substitution of Ta for Ti site can enhance the electronic conductivity of Li$_4$Ti$_5$O$_{12}$ via the generation of mixing Ti$^{4+}$/Ti$^{3+}$, which indicates that Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ is a promising candidate material for anodes in lithium-ion battery application.

Key words: lithium-ion battery; lithium titanate; anode material; doping

1 Introduction

The ever-growing demand for portable batteries with high energy density is exerting pressure for the development of advanced lithium-ion battery. For large-scale applications such as electric and hybrid vehicle systems, the vital issue is the availability of advanced materials. In recent years, there has been considerable effort devoted to developing high energy density, safe and reliable new materials to use as the anodes in lithium-ion battery [1]. The spinel Li$_4$Ti$_5$O$_{12}$ has been found to be an attractive anode material for lithium-ion battery [2–4]. In the lithium titanate spinel-type structure of Li$_4$Ti$_5$O$_{12}$, the formal valence of titanium is +4, which is the highest achievable oxidation state possible for titanium. This Li$_4$Ti$_5$O$_{12}$ material has been found to intercalate lithium ions without strain or shrinkage to the lattice. It has a flat Li insertion potential at about 1.55 V (versus Li$^+$/Li), above the reduction potential of common electrolyte solvents, mitigating the formation of solid-electrolyte interface (SEI) and avoiding formation of lithium dendrites to make the battery safer. However, several disadvantages exist compared with graphite, including the poor electric conductivity that limits its full capacity at high charge-discharge rates.

Effort has been expended to improve the conductivity. Several methods were proposed: 1) doping Li$_4$Ti$_5$O$_{12}$ with other metal cations or non-metal ions in Li, Ti or O sites [5–11]; 2) incorporating a second phase with high electronic conductivity such as carbon and metal powder [12–14]; 3) making a nitridation to form oxynitride species on its surface [15]. However, to our best knowledge, there are less investigations on the electrochemical characteristics of Ta-doped Li$_4$Ti$_5$O$_{12}$ as an anode material. In this work, we proposed to partially substitute Ti$^{4+}$ with Ta$^{5+}$, which will cause a transition of a certain amount of Ti$^{4+}$ to Ti$^{3+}$ as charge compensation. The transition from Ti$^{4+}$ to Ti$^{3+}$ in Li$_4$Ti$_5$O$_{12}$ will lead to an increase in the electronic conductivity and thus improve the rate performance.

2 Experimental

2.1 Preparation of materials

Li$_4$Ti$_5$O$_{12}$ samples were prepared using a solid-state method from TiO$_2$ (anatase structure) and LiOH·H$_2$O. The Ta-doped Li$_4$Ti$_5$O$_{12}$ was prepared also using a solid-state method with TiO$_2$ (anatase structure), LiOH·H$_2$O and Ta$_2$O$_5$. In both cases, mass fraction excess LiOH·H$_2$O was used to compensate for lithium volatilization during the high temperature heating. A doping level of 1% (mole fraction) Ta was selected,
which yields the following composition, Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$, assuming that Ta sits on a Ti site. This is probably a good assumption in that the ionic radius of Ta$^{5+}$ is 0.064 nm, similar to the ionic radius of Ti$^{4+}$ (0.061 nm) and much smaller than the ionic radius of Li$^+$ (0.076 nm). Powders of the precursor materials were mixed in a mortar and pestle with enough methanol to form slurry. The undoped mixed reactant mixture was heated at 800 °C for 5 h in air (oxidizing) and the Ta-doped mixed reactant mixture was heated at 800 °C for 5 h in 3% (volume fraction) H$_2$/Ar (reducing) to obtain the final powders.

2.2 Characterization

The crystal structure of the powders was characterized by X-ray diffraction (XRD, Rigaka Dmax-RB) using Cu-K$_\alpha$ radiation ($10^\circ<2\theta<90^\circ$). Cell parameters were refined with the program FULLPROF [16]. Scanning electron microscope (SEM, KYKY2800) was used to study the morphology of the materials.

2.3 Electrochemical tests

The electrochemical cycling performances of the Li$_4$Ti$_{5}$O$_{12}$ powders were evaluated at room temperature (20 °C) with laboratory-scale Li/Li$_4$Ti$_{5}$O$_{12}$ button cells including a lithium metal foil as counter electrode, a composite of 80% (mass fraction) Li$_4$Ti$_{5}$O$_{12}$, 10% (mass fraction) acetylene black (AB), and 10% (mass fraction) polytetrafluoroethylene (PTFE) binder as a cathode. A micro-porous polypropylene film (Celgard 2400) was used as a separator and 1 mol/L LiPF$_6$ solution with the 1:1 in volumetric ratio of ethylene carbonate to dimethyl carbonate (EC-DMC) was used as the electrolyte. All cells were assembled inside a glove box filled with ultra-pure argon. Charge-discharge characteristics of the cells were recorded in the potential range of 1.0−3.0 V using a LAND batteries test system (CT2001A, Jinmu Electronics Co., Ltd., Wuhan, China) and specific capacities were calculated based on the mass of Li$_4$Ti$_{5}$O$_{12}$. Electrochemical impedance spectrum (EIS) was also measured using a potentiostat/galvanostat EG&G 273A coupled to a frequency response analyzer (FRA) EG&G 1025. The impedance data were obtained between 1 MHz and 10 mHz at 5 mV as the applied sinusoidal perturbation. Electrical resistance measurement of the sintered and polished pellets of Li$_4$Ti$_{5}$O$_{12}$ was also performed at electrochemical workstation above.

3 Results and discussion

3.1 Phase characteristics

The color of the synthesized Li$_4$Ti$_{5}$O$_{12}$ powder is white. The XRD patterns of the Li$_4$Ti$_{5}$O$_{12}$ and Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ are shown in Fig. 1(a). All the sharp diffraction peaks can be attributed to the cubic spinel structure of Li$_4$Ti$_{5}$O$_{12}$ without obvious impurity phase, which indicates that Ta$^{5+}$ has successfully entered the lattice of the spinel and do not change its structural characteristics. The XRD pattern reveals that the (111) peak of the Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ shifted to smaller angels. For a clear observation, the peak position variation of (111) plane is magnified and shown in Fig. 1(b). The XRD refinement according to the Rietveld method indicates that the lattice parameter of Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ is 8.368 Å and that of the Li$_4$Ti$_{5}$O$_{12}$ is 8.362 Å [17], which are consistent with results reported by WOLFENSTINE and ALLEN [10]. The doping of Ta will cause the lattice constant to become large. This may be caused by the reason that the substitution of Ta$^{5+}$ for Ti$^{4+}$ site will cause the transition of a certain amount of Ti$^{4+}$ to Ti$^{3+}$ as charge compensation [10], which will cause the increase of the lattice constant of the Li$_4$Ti$_{5}$O$_{12}$ because Ti$^{3+}$ (0.067 nm) is larger than Ti$^{4+}$ (0.061 nm). For heat-treatment under reducing conditions, according to charge neutrality

![Fig. 1 XRD patterns of Li$_4$Ti$_{5}$O$_{12}$ and the Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ (a) and magnified (111) peaks of Li$_4$Ti$_{5}$O$_{12}$ and Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ (b)]
condition (Kroger-Vink notation [16]) is given in Eq. (1) and hence, an increase in electronic conductivity occurs [10].

\[ e^\prime = [TaTi\cdot] \]  

(1)

where an electron, \( e^\prime \), corresponds to Ti\(^{3+}\) on a Ti\(^{4+}\) site.

3.2 Morphology

Figure 2 shows the SEM images of the undoped Li\(_4\)Ti\(_5\)O\(_12\) powders and the Ta-doped powders. The grains of pure Li\(_4\)Ti\(_5\)O\(_12\) are small with the size generally distributed in the range of 200−300 nm. Small particles will enlarge the contact areas between grains and electrolyte, and thus improve the specific capacity of the electrode. In Fig. 2(b), the grain size of the Ta-doped powders is larger than the pure one, but is also nano-sized.

![Fig. 2 SEM images of Li\(_4\)Ti\(_5\)O\(_12\) (a) and Li\(_4\)Ti\(_{4.95}\)Ta\(_{0.05}\)O\(_12\) (b)](image)

The acquisition of these homogeneously nano-sized Li\(_4\)Ti\(_5\)O\(_12\) powders could be attributed to the precursor material, nano-sized anatase structure TiO\(_2\), which could be mixed more sufficiently with the other materials compared with the usually used micro-sized rutile structure TiO\(_2\). The sintering time in this work is much shorter than the ordinarily reported 10−15 h. Short sintering time was also critical to prevent the grains from excessive growth.

3.3 Electrochemical performance

The electrochemical properties of the powders are determined by charge-discharge test at constant current density. Figure 3 shows the first charge-discharge curves of the undoped and Ta-doped Li\(_4\)Ti\(_5\)O\(_12\) powders at 0.1\(C\) rate in potential window between 3.0 and 1.0 V. The cycling behavior is typical of LTO with a flat plateau at an average potential of 1.55 V which is attributed to a two-phase phenomenon pertaining to Li\(_4\)Ti\(_5\)O\(_12\) and Li\(_7\)Ti\(_5\)O\(_12\) phases. The voltage platform is the result of an adjustment of the above intercalation and deintercalation processes. The sharp and linear increases of the voltage at the end of the charge and the start of the discharge curves are results of electrode polarization. The cation distribution in Li\(_4\)Ti\(_5\)O\(_12\) and Li\(_7\)Ti\(_5\)O\(_12\) phases during electrochemical charge-discharge processes could be written as follows [2]:

\[ [\text{Li}]_{8a}[\text{Li}_{1/3}\text{Ti}_{5/3}]_{16d}[\text{O}_4]_{32e} + \text{Li}^+ + e^- = [\text{Li}_{2}]_{16c}[\text{Li}_{1/3}\text{Ti}_{5/3}]_{16d}[\text{O}_4]_{32e} \]  

(2)

During the first discharge, undoped Li\(_4\)Ti\(_5\)O\(_12\) takes about 2.78 Li atoms, corresponding to a capacity of 161.9 mA·h/g that matches well with the expected theoretical capacity for Li\(_4\)Ti\(_5\)O\(_12\). However, the Ta-doped Li\(_4\)Ti\(_5\)O\(_12\) takes about 2.69 Li atoms, corresponding to a capacity of 156.7 mA·h/g, less than the undoped one. A small electrode polarization of about 0.02 V is observed between charge-discharge curves, indicating the existence of good interparticle electrical contacts and ion transport. In Li\(_4\)Ti\(_5\)O\(_12\) structure, 75% Li\(^+\) ions locate at tetrahedral 8a sites, 25% Li\(^+\) and Ti\(^{4+}\) are randomly distributed at octahedral 16d sites, and O\(^2\) ions occupy the 32e sites, the 8b, 48f and 16c sites are empty [2]. During lithiation process, 3 Li-ions can be accommodated by Li\(_4\)Ti\(_5\)O\(_12\), which will make spinel Li\(_4\)Ti\(_5\)O\(_12\) transform to rock-salt Li\(_7\)Ti\(_5\)O\(_12\). In this process, all Li-ions, including those in 8a site and the newly inserted ones, will move and occupy the 16c site, and
then all octahedral sites are filled. Ta-doping may impede the transportation of Li-ions from 8a to 16c sites, influencing the insertion of outside Li-ions into Li$_4$Ti$_5$O$_{12}$ structure. As a consequence, the capacity of Ta-doped Li$_4$Ti$_5$O$_{12}$ is decreased.

High rate performance is one of the most important electrochemical characteristics of lithium ion batteries for HEV application. The charge-discharge capacities of pure Li$_4$Ti$_5$O$_{12}$ and Ta-doped Li$_4$Ti$_5$O$_{12}$ electrodes at different current rates from 0.1C to 30C are shown in Fig. 4. It can be seen that, the rate performance of Li$_4$Ti$_5$O$_{12}$ can be improved by doping Ta. The charge and discharge capacities decrease with increasing the current rate. Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ exhibits an excellent rate capability compared with Li$_4$Ti$_5$O$_{12}$, although Li$_4$Ti$_5$O$_{12}$ shows much more initial capacity than Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$. At 0.1C, Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ presents a discharge capacity of 152.8 mA·h/g, while the Li$_4$Ti$_5$O$_{12}$ exhibits a discharge capacity of 161.9 mA·h/g. At 30C, the discharge capacity of Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ still remains 91.0 mA·h/g, while the capacity of the undoped Li$_4$Ti$_5$O$_{12}$ is only 44.5 mA·h/g. We proposed to partially substitute Ti$^{4+}$ with Ta$^{5+}$, which will cause a transition of a certain amount of Ti$^{4+}$ to Ti$^{3+}$ as charge compensation. The transition from Ti$^{4+}$ to Ti$^{3+}$ in Li$_4$Ti$_5$O$_{12}$ will lead to an increase in the electronic conductivity and thus improve the rate performance.

The cycling performance of the Ta-doped and undoped Li$_4$Ti$_5$O$_{12}$ samples at the rate of 1C is exhibited in Fig. 5. In Fig. 5, more than 11.1% of the capacity loss occurs to the undoped Li$_4$Ti$_5$O$_{12}$ at 1C after 100 cycles, while the Ta-doped Li$_4$Ti$_5$O$_{12}$ loses only 6.3% after 100 cycles. The 100th discharge capacity of the Ta-doped Li$_4$Ti$_5$O$_{12}$ electrode is 146.8 mA·h/g, but the corresponding value of the Li$_4$Ti$_5$O$_{12}$ electrode is decreased to 144.7 mA·h/g. This indicates that the introduction of Ta ions can increase the cycle stability. This suggests that the electrode polarization is probably decreased by Ta-doping.

![Fig. 4 Initial discharge-charge curves of Li$_4$Ti$_5$O$_{12}$ (a) and Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ (b) at different current rates (0.1C, 1C, 5C, 10C, 20C, 30C).](image)

![Fig. 5 Cycling performance of Li$_4$Ti$_5$O$_{12}$ and Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ samples (current rate of 1C).](image)

Electrochemical impedance spectroscopy (EIS) may be considered one of the most sensitive tools for studying the changes in the electrode behavior due to surface modification. EIS results of the coin cells with the Li$_4$Ti$_5$O$_{12}$ and Ta-doped Li$_4$Ti$_5$O$_{12}$ cathodes are shown in Fig. 6. The measurement was carried out after the cells have been discharged to the depth of 50% followed by three cycles. The impedance spectra are composed of one semicircle at higher frequencies followed by linear part at lower frequency end. The semicircle in the high region represents the migration of the lithium ions at the electrode/electrolyte interface. The low frequency region of the straight line is attributed to the diffusion of the lithium ions into the bulk of the electrode material, the so-called Warburg diffusion [18].

The relationship between the imaginary impedance and the low frequencies is governed by Eq. (3). The diffusion coefficients of the lithium ions in the bulk electrode materials were calculated by Eq. (4). The Warburg impedance coefficient can be obtained from the straight lines [17–18]. The relation is governed by Eq. (5).
These calculated results are recorded in Table 1. The real impedance of the Li$_4$Ti$_5$O$_{12}$ and the Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ samples in the low frequencies is illustrated in Fig. 7.

The obtained diffusion coefficients show that Ta-doped Li$_4$Ti$_5$O$_{12}$ sample has higher mobility for Li$^+$ diffusion than the undoped Li$_4$Ti$_5$O$_{12}$ sample. This is attributed to the concentration of electrons caused by the transition of a certain amount of Ti$^{4+}$ to Ti$^{3+}$ as charge compensation. The transition from Ti$^{4+}$ to Ti$^{3+}$ in Li$_4$Ti$_5$O$_{12}$ will lead to an increase in the electronic conductivity and thus improve the rate performance.

4 Conclusions

1) Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ powders have been successfully synthesized by a simple solid state reaction. XRD patterns show that the Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ has a good crystallinity and a high phase purity.

2) The Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ electrode presents better cycling performance than the Li$_4$Ti$_5$O$_{12}$ electrode prepared by the similar process. Ta-doping does not change the phase composition and particle morphology, while improves remarkably its cycling stability at high charge-discharge rate.

3) The substitution of Ta for Ti site can enhance the electronic conductivity of Li$_4$Ti$_5$O$_{12}$ via the generation of mixing Ti$^{4+}$/Ti$^{3+}$. At 30°C, the discharge capacity of the Li$_4$Ti$_{4.95}$Ta$_{0.05}$O$_{12}$ still remains at 91.0 mA h/g, while the capacity of the undoped Li$_4$Ti$_5$O$_{12}$ is only 44.5 mA h/g. More than 11.1% of the capacity loss occurs to the undoped Li$_4$Ti$_5$O$_{12}$ at 1C after 100 cycles, while the Ta-doped Li$_4$Ti$_5$O$_{12}$ loses only 6.3% after 100 cycles. The 100th discharge capacity of the Ta-doped Li$_4$Ti$_5$O$_{12}$ electrode is 146.8 mA h/g, but the corresponding value of the Li$_4$Ti$_5$O$_{12}$ electrode is decreased to 144.7 mA h/g.

锂离子电池极材料钽掺杂钛酸锂的制备及电化学性能

胡国荣，张新龙，彭忠东

中南大学 冶金科学与工程学院，长沙 410083

摘要：通过固相合成制备了钽掺杂材料 Li_{4}Ti_{4.95}Ta_{0.05}O_{12}。通过XRD和SEM来表征 Li_{4}Ti_{4.95}Ta_{0.05}O_{12} 的结构和形貌。钽掺杂并没有改变本体材料的结构和形貌，而且显著提高了材料的循环性能和倍率性能。Li_{4}Ti_{4.95}Ta_{0.05}O_{12} 在10C 和30C 倍率时的放电容量分别是116.1 mAh/g 和91.0 mAh/g。Ta 掺杂取代了 Li_{4}Ti_{5}O_{12} 中的 Ti 的位置，产生了 Ti^{4+}/Ti^{3+} 混合价态，从而提高了钛酸锂的电导率。故具有优异的高倍率性能，是一种优异的锂离子电池负极材料。
